Introduction

Welcome to the Binocular Sky Newsletter of April 2013. The intention of this monthly offering is to highlight some of the binocular targets for the coming month. It is primarily targeted at observers in the UK, but should have some usefulness for observers anywhere north of Latitude 30°N. For this Newsletter to be a useful tool, it needs to have the information that YOU want in it; therefore please do not be shy about making requests – if I can accommodate your wishes, I shall do so.

From this issue, I have changed the colours of the “normal” format, so there is no longer a need for a “printer-friendly” version.

If you would like me to email this newsletter to you each month, please complete and submit the subscription form. You can get “between the newsletters” alerts, etc. via [Facebook] and [Twitter].

Transient Objects

Comet C/2011 L4 (PanSTARRS) is dimming very rapidly and I estimated it to be about magnitude 4 in the pre-dawn of 29th March. At the rate at which it is declining in brightness, it could be below 10th magnitude by the end of the month. Fortunately, it passes some useful markers during the course of the month, so locating it, if it remains visible, should be relatively simple.
Transient Objects (contd)

The Deep Sky

The Deep Sky ([hyperlinked text](#) will take you to charts and more information.)

The **Pleiades** (M45) and the **Great Orion Nebula** (M42) culminate before Civil Twilight ends, but are still fine sights in binoculars early in the month, as are the trio of open clusters in Auriga and M35 in Gemini. While you are looking at M35, also see if you can identify two smaller open clusters, NGC 2158, which is half a degree to the SE, and the slightly more difficult IC 2157, which is a degree to the ESE. Also high are M44 (**Praesepe**) and M67, two fine open clusters in Cancer. Lower in the southern sky are more open clusters M46 & M47 and, near Sirius, M41.
Open (also called ‘Galactic’) Clusters are loosely packed groups of stars that are gravitationally bound together; they may contain from a few dozen to a few thousand stars which recently formed in the galactic disk.

In April, we are able to look out of the plane of the Galaxy during the evening. This makes more globular clusters and galaxies available for observation. Look out for the two galaxy trios in Leo ([M95/96/105] and [M65/66/NGC3628]) and Markarian’s Chain in Coma Berenices. If you have a big binocular, also observe the edge-on [NGC4565] (Berenice's Hair Clip), which is next to Melotte 111, the cluster that gives Coma its name. You should find [M81] (Bode's Nebula) and [M82] (The Cigar Galaxy) easy in a 50mm binocular. These can be used as a good demonstration of averted vision: if you have them both in the same field of view, you may see that the core of M81 becomes more apparent if you look at M82. If you have good skies, try [M51] (The Whirlpool), [M94] and [M63] (The Sunflower). M63 really needs a 70mm or larger binocular in anything other than pristine skies.

The globular cluster [M3] is a good one to start with during an April evening's observing. Later in the evening, the two Hercules globulars, [M92] and the very impressive, and very easy to find, [M13] are at a better altitude for observation.

Globular clusters are tightly-bound, and hence approximately spherical, clusters of tens, or even hundreds, of thousands of stars that orbit in a halo around almost all large galaxies that have been observed. They are important for two reasons: Firstly, they contain some of the oldest stars in the galaxy, so studying them helps us understand the evolution of stars. Secondly, they are useful as “standard candles” in establishing a distance scale of the Universe, based on the assumption that the brightest stars in any globular cluster will be approximately the same brightness and that the brightest globulars in a galaxy will be approximately the same brightness.
If you have binoculars of 70mm aperture or (preferably) greater, see if you can find and identify *The Ghost of Jupiter (NGC 3242)*, a planetary nebula in Hydra. It is a difficult object because it is low in the sky, even from southern Britain.

*Planetary Nebulae are short-lived (a few tens of thousands of years) masses of gas and plasma that result from the death of some stars. They have nothing to do with planets, but get their name from the fact that, in early telescopes, they had the appearance of giant planets.*

**The Solar System**

**Planets**

The binocular planets, Neptune and Uranus, are not observable this month.

**Minor Planets**

Asteroids 1 *(Ceres)* and 4 *(Vesta)* are fading slowly at magnitudes 8.7 and 8.3 (mid-month) respectively, but are both observable after twilight ends, ideally with 15x70 or larger binoculars.

Vesta has a close encounter with the Gemini clusters at the end of the month.
Lunar Occultations

There are no occultations of bright stars visible from the UK this month.

Meteor Showers

A waxing gibbous Moon interferes with the April Lyrids, which peak on the morning of the 22\textsuperscript{nd}. The best time to observe will be for about 40 minutes after the Moon sets at 03:10 UT, by when astronomical twilight will have begun. They usually peak at 20-30/hr, but have sometimes had outbursts of over 100/hr, which makes them very much worth watching. These meteors are dust particles from the tail of Comet Thatcher. As these particles enter the atmosphere, they compress and heat the air in front of them. This heat causes the
surface of the particle to ablate and ionise. Binoculars are useful for observing the persistence of these ionisation trains that form the streak in the sky which is what we observe as a “shooting star”.  

The Moon  

Apr 03  Last Quarter  
Apr 10  New Moon  
Apr 18  First Quarter  
Apr 25  Full Moon  

Wishing you Clear Dark Skies,  

**Steve Tonkin for The Binocular Sky**
