

The Binocular Sky

No. 125
May 2022

Newsletter

Introduction

Welcome to May's **Binocular Sky** Newsletter.

As regular readers will know, my intention is to highlight some of the binocular targets for the coming month. This is primarily intended for visual astronomers, with binoculars or small telescopes, in the UK, but it should have some utility for observers anywhere north of Latitude 30°S and possibly even further south (if you are further south, please let me know!)

In the Solar System, we have lost the ice giants, Uranus and Neptune, into the solar glare, but **Mercury** is within the range of small binoculars early in the month.

Comet C/2017 K2 (PanSTARRS) is now within range of medium binoculars.

In the deep sky, the "realm of galaxies" is now very convenient for evening observation and the more southerly zodiacal constellations are becoming visible in the pre-dawn.

If you would like to receive the newsletter automatically each month, please complete and submit the [subscription form](#). You can get "between the newsletters" alerts, etc. via  and .

The Deep Sky

(Hyperlinks will take you to finder charts and more information on the objects.)

The [trio of open clusters](#) in Auriga and [M35](#) in Gemini are still visible low in the West as twilight darkens. While you are looking at [M35](#), also see if you can identify two smaller open clusters, [NGC 2158](#), which is half a degree to the SE, and the somewhat more difficult [IC 2157](#), which is a degree to the ESE. Also in the West, but slightly higher are [M44](#) ([Praesepe](#)) and [M67](#), two fine open clusters in Cancer.

[M67](#) is interesting from an astrophysics perspective, as it contains numerous Sun-like stars, so their study aids our understanding of our own star.

[NGC 457](#) ([The Owl Cluster](#)) and [NGC 663](#) in Cassiopeia and the [Perseus Double Cluster](#) are also visible in the north. The finest and best-placed open cluster available this month is [Melotte 111](#), the cluster that gives Coma Berenices its name.

Towards midnight, or later, the open clusters in the summer Milky Way such as [IC 4665](#) ([the Summer Beehive](#)), [Melotte 186](#) ([Poniatowski's Bull](#)), and [M11](#) ([the Wild Duck cluster](#)) are better placed.

In May, we are able to look out of the plane of the Galaxy during the evening. This makes more globular clusters and galaxies available for observation. Look out for the two galaxy trios in Leo ([M95/96/105](#) and [M65/66/NGC3628](#)) which are now moving into the western sky, and [Markarian's Chain](#) in Coma Berenices, which is very well placed as we enter astronomical twilight. If you have a big binocular, also observe the edge-on [NGC4565](#) ([Berenice's Hair Clip](#)), which is next to [Melotte 111](#). Also very well placed this month are [M81](#) ([Bode's Nebula](#)) and [M82](#) ([The Cigar Galaxy](#)), both of which are easy in a

Open (also called 'Galactic') Clusters are loosely packed groups of stars that are gravitationally bound together; they may contain from a few dozen to a few thousand stars which recently formed in the galactic disk.

Galaxies are gravitationally bound "island universes" of hundreds of billions of stars at enormous distances. The light that we see from [M31](#), for example, left that galaxy around the time our technology consisted of rocks, sticks and bones.

50mm binocular. These can be used as a good demonstration of averted vision: if you have them both in the same field of view, you may see that the core of M81 becomes more apparent if you look at M82. If you have good skies, try M51 (The Whirlpool) and M101 which, although it is a large object, is very difficult owing to its low surface brightness and, therefore, lower

contrast against the background sky.

You'll see from the chart that the globular clusters are becoming better placed in the evening. Of these, M3 is a good one to start with during a May evening's observing. Later in the evening, the two Hercules globulars, M92 and the very impressive and very easy to find M13 are at a better altitude for observation. Although M13 is clearly larger than M92, it is easier to resolve the outer stars of the latter one. M5 and M53 are also well placed in May evenings and, later in the night the Ophiuchus globulars become easier. You can use the same averted vision "trick" suggested for M81 & M82 with M10 and M12 to enhance the distinctly brighter core of M10.

Globular clusters are tightly-bound, and hence approximately spherical, clusters of tens, or even hundreds, of thousands of stars that orbit in a halo around almost all large galaxies that have been observed.

If you have binoculars of at least 100mm aperture, see if you can find and identify NGC 4361, a planetary nebula in Corvus. It is a difficult object because it is low in the sky, even from southern Britain. Another planetary nebula that is a challenge is NGC 6572 in Ophiuchus. It looks stellar, even at 40x, but you can identify it by its colour; I see it as green, but apparently younger people can see it as blue.

Planetary Nebulae are short-lived (a few tens of thousands of years) masses of gas and plasma that result from the death of some stars. They have nothing to do with planets, but get their name from the fact that, in early telescopes, they had the appearance of giant ghostly planets.

For interactive maps of Deep Sky Objects visible from 51°N, you can visit: https://binocularsky.com/map_select.php

Planets

The binocular planets, **Uranus** and **Neptune**, are not visible this month, but binoculars will help you tease naked-eye **Mercury** out of the evening twilight at the beginning of the month, when it is just 2° E of the Pleiades.

Comets

The perihelion approach of Comet C/2017 K2 (PanSTARRS) has been hotly anticipated for some time. It hasn't brightened as quickly as expected, but is near mag. +10, which is in easy reach of 70mm aperture and upwards, given a decent sky. At the beginning of the month, it is about 45° high (from latitude 51°N) at the end of astro-dark.

Of course, precise comet brightness is highly unpredictable, but it should keep brightening as it passes southward through Ophiuchus over the coming months, so southern observers will get the best of it.

Public Outreach & Talks

If you find yourself at any of these, do give me a virtual “wave”. Dates are UT.

Zoom/Webex Talks?

I regularly give talks, on *Binocular Astronomy* and numerous other astronomical topics. I’d be happy to do this – potentially anywhere in the world – on Zoom or Webex if that is of interest.

If you would like a talk for your society/group, [Click here for current talks.](#)

For schools/scouts/guides, etc., I am a STEM Ambassador so there will be no fee.

The **Binocular Sky Newsletter** will always be free to anyone who wants it, but if you would like to support it, there are a number of options:

- Purchase one of my books, **Binocular Astronomy** or **Discover the Night Sky through Binoculars.**
- Make a small PayPal donation to newsletter@binocularsky.com

Wishing you Clear Dark Skies,

Steve Tonkin
